

Dashboard Spec — Simulated Product Analytics (Looker Studio)

Audience: InGen product + ops + sales. Built on the Week 7 synthetic warehouse (no real InGen data).

Question it answers

“How healthy is the fleet, how is support performing, and how is the sales pipeline tracking — by product line and over time?” Answered on the first screen via a KPI band + six panels.

Layout & panels

Section	Panels
KPI band	Active robots · avg uptime/day · tickets · avg CSAT · won value (scorecards)
Fleet health	Uptime trend by product (line) · total errors by product (bar)
Support	Avg resolution hours by severity (bar) · (drill: by category)
Sales	Won value by month (area) · win rate by product (bar) · avg CSAT by product (bar)

Data sources (upload-ready extracts)

data/week08/extracts/: fleet_health_daily.csv, support_performance.csv, sales_pipeline.csv, kpi_summary_by_product.csv — all aggregated directly from the Week 7 DuckDB warehouse.

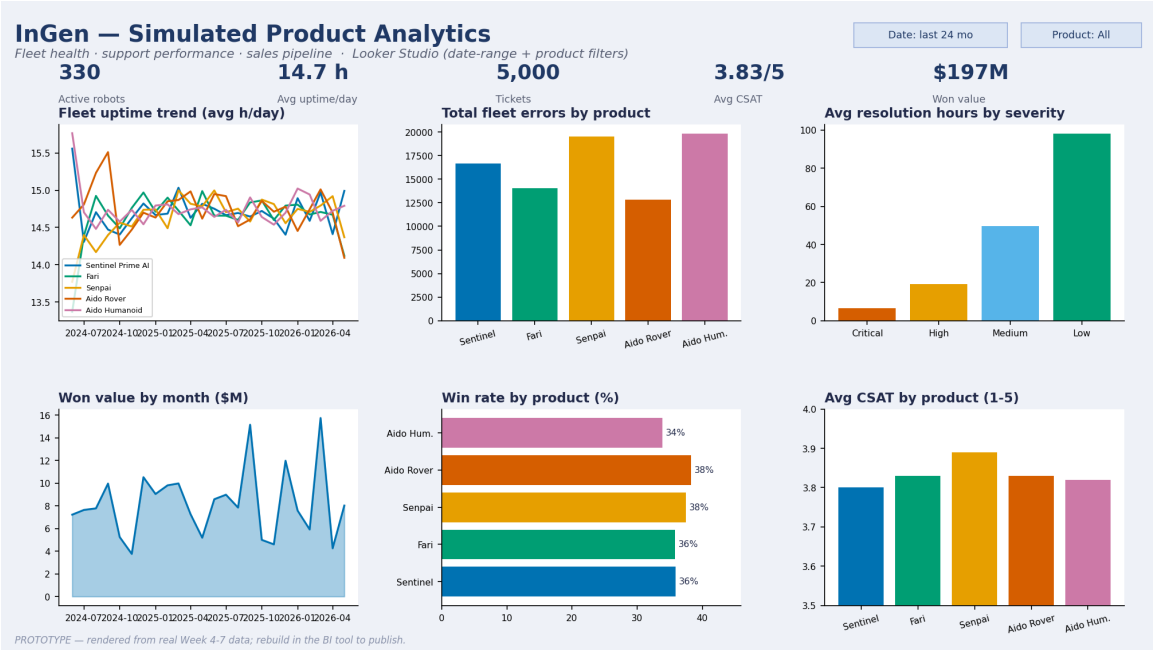

Filters & interactions

Date-range control (default last 24 months) and **Product-line** filter (All / each of the five). Both apply to every panel; the KPI band recomputes on filter change. Date and product keys exist in every extract, so no broken states.

Chart types (and why)

Lines for trends over time; bars for per-product comparison; area for cumulative monthly bookings; scorecards for headline KPIs. Severity uses an ordered Critical→Low scale with a sequential color ramp.

Prototype

Success criteria (from plan)

Loads <5s · answers its question on the first screen · color-blind-safe palette · date + product filters update all charts coherently. Publishing produces the Looker Studio share link (user's account).
